

WHERE THE LEGACY GRID FAILS - AND WHAT THE ADJUSTMENT CHANGES

Data-free numerical study | same Landau-Gaussian formula, MPV = 0, area = 1, integration from x-5 sigma to x+5 sigma

Columns: Landau width (ADC). Rows: Gaussian sigma (ADC). Difference = max |legacy - adjusted| / adjusted peak.
Red outline: near the E1 cell 896 narrow-width fit (Landau width 0.122, Gaussian sigma 7.889).

Adjusted count: next even integer $\geq \max(100, 50 \text{ sigma} / \text{Landau width})$, capped at 10,000.
Hidden fine-grid check: at least 20 samples per Landau width; adjusted result differs by less than 0.01% of peak throughout this grid.
